## Definition 1.1

*Pulse Width Modulation (PWM) is a technique used to control the amount of power delivered to a device by modulating the width of the pulses in a signal. PWM achieves this by switching the signal between on and off states, and adjusting the amount of time the signal stays on within each period (duty cycle).*

## Key Characteristics:

- **Frequency:** The number of times the PWM signal repeats per second.
- **Duty Cycle:** The proportion of the signal period during which the signal is high (on), typically expressed as a percentage.
- **Applications:** PWM is used in controlling motors, dimming LEDs, and regulating power in electronic devices.

# CAN - Controller Area Network

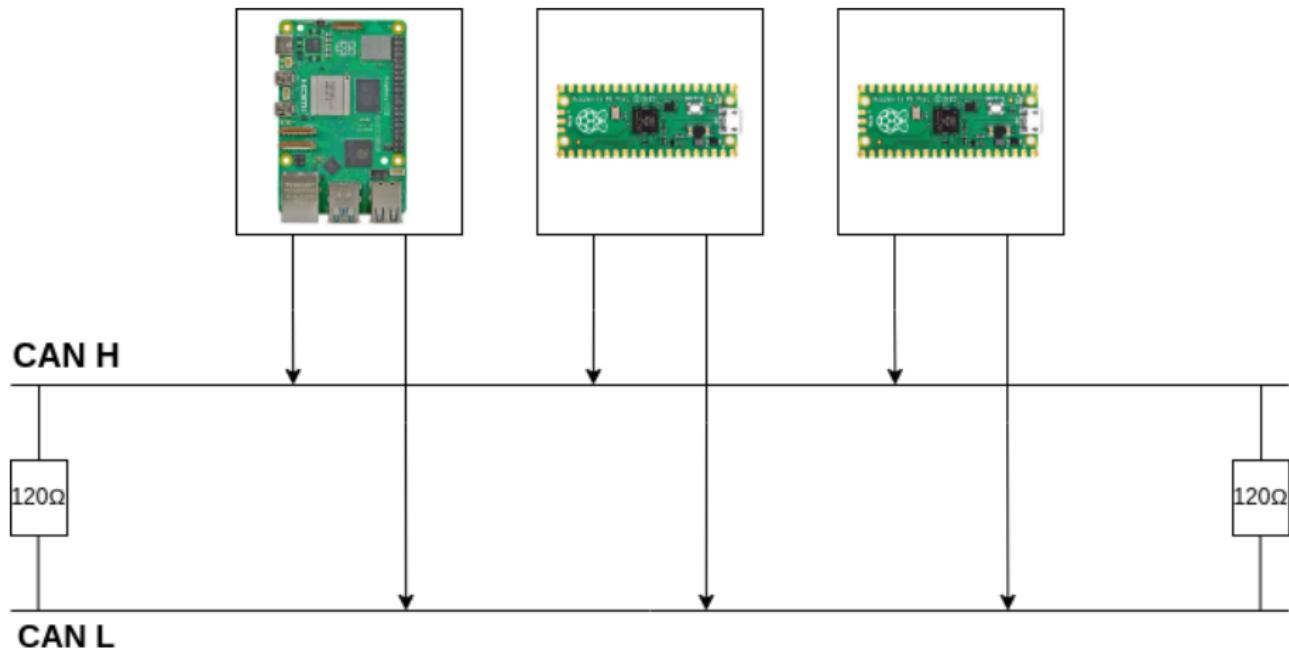

Figure 2.1: Can-Bus Architecture

# CAN - Node Architecture

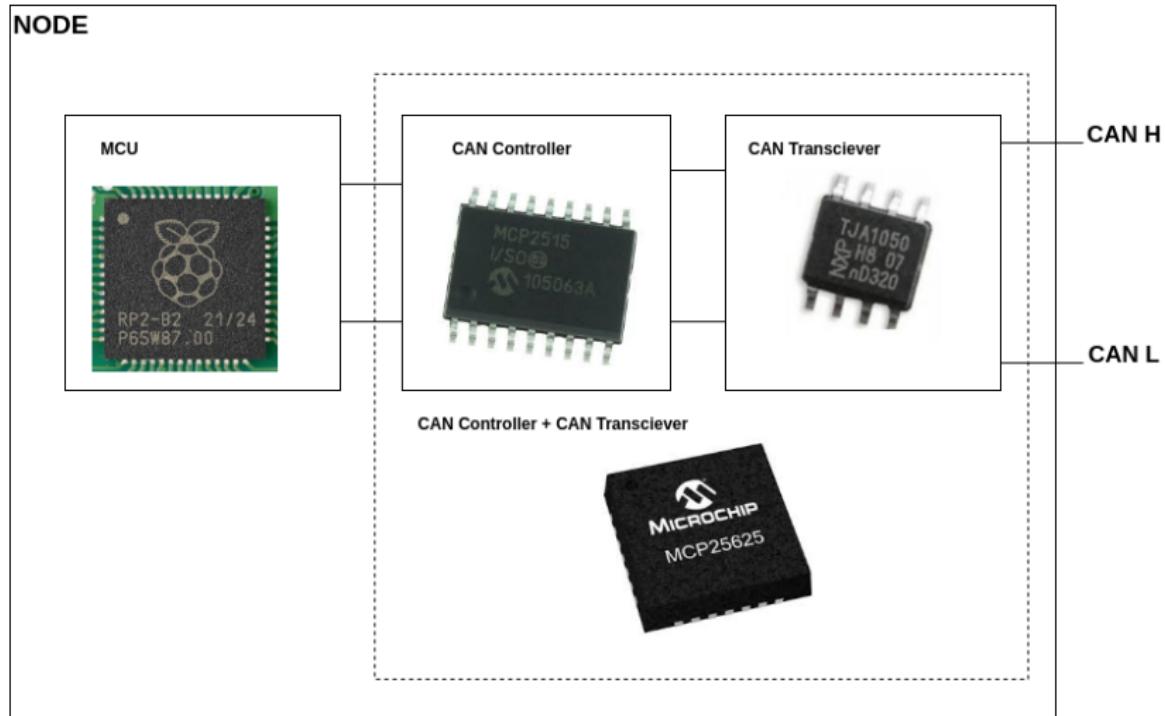

Figure 2.2: Can-Bus Architecture

# CAN - Advantages of High-Speed CAN

- **Increased Data Transfer Rate**
  - Supports data rates up to 1 Mbps, allowing faster communication between nodes.
- **Efficient Error Handling**
  - Implements sophisticated error detection and handling mechanisms to ensure data integrity.
- **Robustness**
  - Highly resilient to electrical noise and interference, making it suitable for automotive and industrial applications.
- **Real-Time Performance**
  - Provides deterministic response times, which is crucial for time-sensitive applications.

# CAN - Frame Structure

Start of Frame	Identifier	Control	Data	CRC	ACK	End of Frame
1 bit	11 bits (Standard)	6 bits	0-8 bytes	15 bits	2 bits	7 bits

## Description des champs :

- **Start of Frame:** Indicates the beginning of the frame (1 bit).
- **Identifier:** Contains the message ID (11 bits for standard format).
- **Control:** Contains control bits, including the length of the data.
- **Data:** Data to be sent, between 0 and 8 bytes.
- **CRC:** Cyclic Redundancy Check code for error detection (15 bits).
- **ACK:** Acknowledgement field (2 bits).
- **End of Frame:** Indicates the end of the frame (7 bits).

# SWD - Single Wire Debug

## Definition 2.1 (SWD)

*The SWD protocol operates using a **request-response** structure. The host (usually a debugger or programming tool) sends a request to the target device (the microcontroller), and the target responds accordingly.*

The protocol supports different operations like:

- reading/writing memory,
- accessing peripheral registers,
- halting/resuming execution, and
- managing breakpoints.

# SWD - Architecture

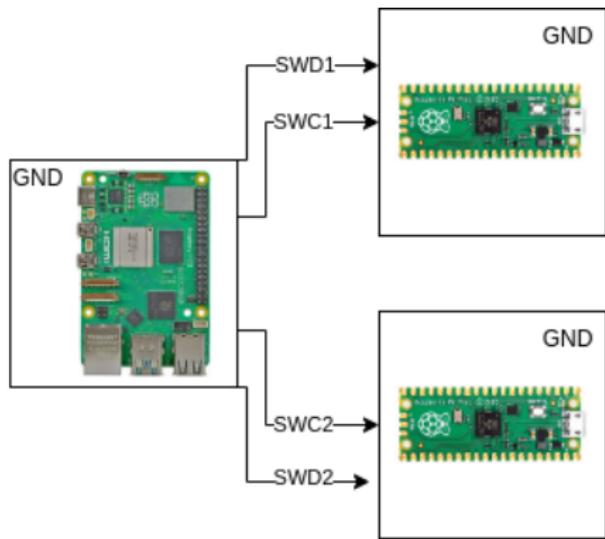

Figure 2.3: Can-Bus Architecture

- **SWDIO:** The main data line used for bidirectional data transfer. It carries both command and response data between the debugger and the target.
- **SWCLK:** The clock signal that synchronizes data transmission. It is used by the debugger to time the sending and receiving of data on the SWDIO line.
